First, the data was loaded in, a variable for state and city was created, and then filtered down to only
Baltimore, MD. Then the date variable was created by converting the reported date to year-month format.
A logical vector of whether or not the month was a winter month was generated using another new column
of only the month. `group_by()` and `count()` functions were used to create the total homicides for each
year-month. Finally the graph was plotted using `geom_col()`, `geom_vline()`, and `geom_smooth()` with
adjustments made to the scale, theme, labels, and reference text.
